Due to probability of Cesarean scar pregnancy in every pregnant woman with history of even one previous Cesarean section, it is strongly suggested that early in pregnancy in these patients abdominal or vaginal scan for determination of the location of pregnancy is performed. Cesarean scar pregnancy may cause preventable morbidity or even mortality in mothers, so early diagnosis is mandatory. Many of these cases have no symptoms. So it is suggested that at least one scan at around 6 weeks of pregnancy is performed for determination of the location of pregnancy. If we are suspicious whether gestational sac is in the lower segment of uterus or not, it is suggested to rescan in 1 week, and also even taking second opinion about the nature of the pregnancy.

Because there is no definite sign that indicates in which cases it is impossible to have Cesarean scar pregnancy, this screening scan should be performed for every previous caesarean section patients.
