**Objective:**
To establish the risk of preeclampsia among women with history of congenital heart disease (CHD) and to compare it to the risk among unselected population.

**Methods:**
A systematic search was performed to identify relevant studies published in English, Spanish, French, Chinese, German, and Polish, with no time restrictions.

**Inclusion criteria:**
- Observational studies of pregnant women with CHD and evaluation of obstetric outcomes

**Conclusions:**
- The risk of preeclampsia among women with CHD is 2.9% (2% - 3.8%), which is similar to the risk among unselected population (Risk: 1.9%; 95% CI: 1.27% - 2.6%).
- History of CHD is at most, a mild risk factor for preeclampsia.

**[EP 02.17]. Is cardiac maladaptation a risk factor for preeclampsia?**
